## Discrete Models

Suppose that a time series of  $q + 1$  data points

$$y_0, y_1, y_2, \dots, y_q$$

is given. A *likelihood function*  $L$  gives the probability that the observed data would result from the proposed stochastic mechanism relative to all other possible outcomes [132]. The data  $y_t$  is a realization of the random variable  $x(t)$ . On the log scale,  $w_t = \ln y_t$  is a realization of the random variable  $\ln x(t)$ . The likelihood function  $L$  is

$$L(\theta_1, \dots, \theta_p, \nu) = \prod_{t=1}^q p(w_t | w_{t-1}),$$

where  $p(w_t | w_{t-1})$  is the joint probability distribution function (pdf) that  $w_t$  occurs given that  $w_{t-1}$  occurs. This is a normal pdf with mean  $\ln f(y_{t-1}, \theta_1, \dots, \theta_p)$  and variance  $\nu$ . Thus,

$$p(w_t | w_{t-1}) = \frac{1}{\sqrt{2\pi\nu}} \exp\left(-\frac{1}{2\nu} (w_t - \ln f(y_{t-1}, \theta_1, \dots, \theta_p))^2\right)$$

and

$$L(\theta_1, \dots, \theta_p, \nu) = \prod_{t=1}^q \frac{1}{\sqrt{2\pi\nu}} \exp\left(-\frac{1}{2\nu} (w_t - \ln f(y_{t-1}, \theta_1, \dots, \theta_p))^2\right).$$

The *maximum likelihood parameter estimates* are those values of the parameters  $\theta_1, \dots, \theta_p, \nu$  that maximize  $L(\theta_1, \dots, \theta_p, \nu)$ , or equivalently that maximize  $l(\theta_1, \dots, \theta_p, \nu) \doteq \ln(L(\theta_1, \dots, \theta_p, \nu))$ . A calculation shows

$$l(\theta_1, \dots, \theta_p, \nu) = -\frac{q}{2} \ln(2\pi) - \frac{q}{2} \ln \nu - \frac{1}{2\nu} \sum_{t=1}^q r_t^2(\theta_1, \dots, \theta_p),$$

where

$$r_t(\theta_1, \dots, \theta_p) \doteq \ln y_t - \ln f(y_{t-1}, \theta_1, \dots, \theta_p) = \ln\left(\frac{y_t}{f(y_{t-1}, \theta_1, \dots, \theta_p)}\right)$$

are the log-residuals. The critical points  $(\theta_1, \dots, \theta_p, \nu)$  of  $l$  are zeroes of the derivatives

$$\partial_{\theta_i} l = -\frac{1}{\nu} \sum_{t=1}^q r_t(\theta_1, \dots, \theta_p) \partial_{\theta_i} r_t(\theta_1, \dots, \theta_p),$$

$$\partial_{\nu} l = -\frac{q}{2} \frac{1}{\nu} + \frac{1}{2\nu^2} \sum_{t=1}^q r_t^2(\theta_1, \dots, \theta_p),$$

i.e., are roots of the uncoupled equations

$$\sum_{t=1}^q r_t(\theta_1, \dots, \theta_p) \frac{\partial_{\theta_i} f(y_{t-1}, \theta_1, \dots, \theta_p)}{f(y_{t-1}, \theta_1, \dots, \theta_p)} = 0,$$
